QuestPage

The Agent Memory Infrastructure

Define the Business Idea & Objective

Problem Statement

When using AI Agents for automation, such as Lead Generation, what happens is:

- AI generates incorrect results without us noticing until it's too late to fix.
- Storing data in Notion/Airtable via API is slow and wastes tokens.
- There is no central dashboard for humans to verify before the Agent proceeds to the next step.

The QuestPage POC will test a “Human-in-the-Loop Dashboard” where humans can see raw data from the Agent, edit it immediately, and click approve to send a signal back for the Agent to continue working, without relying on external clouds.

Hypothesis

Humans can receive data from the AI Agent, verify/edit, and approve within the same dashboard with a response time of less than 2 seconds, and without using third-party cloud services.

- If it can be proven that the first group of 3 friends or users feel that "it is useful and practical" → POC Pass → Develop into MVP
- If no one is excited → Pivot or stop without wasting much time.

In-Scope & Out-of-Scope

In-Scope (What needs to be done)

- Simple Backend API to receive POST /api/prospects from a simulated Agent
- Single-page Dashboard UI using SvelteKit to display Lead lists sent by the Agent
- Inline Editing to correct data on screen immediately
- Approve button to send PATCH back to the Backend and update status
- Webhook Callback to send an empty JSON back to the simulated Agent (using a simple secret token)
- Local Database using JSON files (lowdb or custom) for data storage – no PostgreSQL required
- Agent Simulator: a small script that curls Lead data every 5 seconds

Out-of-Scope (Not doing in this POC)

- Real-time sync (SSE/WebSocket) – use page refresh instead
- RxDB, SvelteKit, Prisma, Deno, HMAC (advanced features)
- Login/User system
- MCP Server, Agent Tracing
- Load Testing, detailed KPIs
- Beautiful UI customization, Responsive design

Simplified Tech Stack

Backend	Node.js + Express.js	Familiar, fast learning curve
Database	DEV	0s installation, no config needed
Frontend	Need to scroll through JSON or chat messages	No compile needed, immediate updates
Agent จำลอง	Localhost หรือ ngrok	Easiest Agent simulation
Deployment	Must keep Terminal open	Enough for friends to test

Timeline

Monday – Backend + API

- Install Node.js, Init project
- Create server.js with Express
- API POST /api/prospects: Receive JSON and save to db.json
- Test with Postman or curl

Tuesday – Dashboard UI

- Create index.html with table showing data from API
- Fetch data using fetch() and render as a table
- Refresh button

Wednesday – Edit + Approve Flow

- Add Edit button to change values in rows (inline contenteditable)
- Approve button sends PATCH /api/prospects/:id to change status to "approved"
- Webpage updates row immediately

Thursday – Webhook Callback + Agent Simulator

- When Approved, backend sends POST to designated URL (webhook of simulated Agent)
- agent-sim.sh script runs loop sending curl POST every 5s and listens for callbacks
- Test full cycle: Sim → API → UI → Approve → Webhook → Sim

Friday – Testing with Friends & Collecting Feedback

- Deploy via ngrok for 3 friends to access
- Record feedback: “What was frustrating, do you feel safe using it, what else do you want?”
- If at least 2 out of 3 people say “it's useful” → POC Pass

Success Criteria

1. Agent sends data to dashboard within 2s
2. Human corrects data and approves smoothly
3. Webhook is called after Approve and Agent receives it
4. At least 2 out of 3 friends say they “want to keep using it”

Resources Required

- 5 full days of your time (including debugging)
- 1 Computer
- Node.js 18+ installed
- Free ngrok account
- 3 kind friends

Next Steps After POC Passes

- Migrate Database to SQLite (Drizzle ORM) for concurrent support
- Switch UI to React/SvelteKit + proper state management
- Add Real-time support (SSE/WebSocket)
- Prepare for Beta launch to AI Agent developer groups (Discord, Reddit)
- Start user interviews to validate willingness to pay
